Tarea 2: Path Tracing con OpenMP y Numba

> Falta ejecutar este mismo script en un segundo computador fisico y copiar sus resultados a la seccion de comparacion. No se inventan mediciones de hardware no disponible.

Declaracion de uso de IA

Se uso un asistente de IA para revisar la pauta y las clases, implementar las versiones OpenMP/Numba, crear scripts de experimentacion y redactar este informe. Los resultados numericos provienen de ejecuciones locales registradas en `results.csv`.

Resumen del problema

El ray tracing serial calcula iluminacion directa con modelo de Phong, sombras y rebotes especulares. El path tracing agrega rebotes difusos aleatorios en el hemisferio y promedia N caminos por pixel, por lo que el costo crece como O(WHNDK), donde K es el numero de objetos. Cada pixel es independiente: corresponde a un patron map, trivialmente paralelizable en memoria compartida.

La carga por pixel es irregular porque algunos rayos escapan al fondo rapidamente, mientras otros generan cadenas de rebotes, rayos de sombra e intersecciones contra mas objetos. Por eso `schedule(static)` puede dejar threads esperando en la barrera final, mientras `dynamic` o `guided` mejoran el balance a cambio de overhead de planificacion.

Implementacion

`omp_pt.cpp` paraleliza el loop de pixeles con `#pragma omp parallel for`. `omp_pt_sched.cpp` usa `schedule(runtime)` y selecciona `static`, `dynamic` o `guided` con `omp_set_schedule`, lo que permite barrer chunksize sin recompilar. El espacio 2D de pixeles se aplano a un indice `idx`; asi el chunksize representa pixeles y no filas completas. Cada iteracion escribe una posicion unica de `pixels[idx]` y usa un RNG local sembrado con `idx + 1`, por lo que no hay condiciones de carrera.

`numba_pt.py` implementa la misma logica con `@njit(parallel=True)` y `prange`. Numba compila las funciones a codigo nativo con LLVM durante la primera llamada; por eso el script hace un warm-up minimo antes de medir. A diferencia de OpenMP, donde el paralelismo se expresa mediante directivas al compilador C++, Numba traduce una subparte compatible de Python/NumPy y administra sus propios threads. El RNG de Numba es un LCG local por pixel para evitar estado global compartido.

Computador 1

Procesador: Intel(R) Core(TM) i7-9750H CPU @ 2.60GHz

Cores fisicos reportados: 6

Threads logicos reportados: 12

Threads por core: 2

Resultados seriales

Las mediciones usan wall-clock time. Si se piden varias repeticiones con `--reps`, el informe conserva el minimo, siguiendo la recomendacion de clase para reducir ruido experimental.

Comparacion OpenMP vs Numba

Para cada punto paralelo se calcula contra la referencia `serial_pt` de la misma escena y configuracion: `S(p) = Ts / T(p)` y `E(p) = S(p) / p`. Los graficos de tiempo incluyen ademas la curva ideal `Ts / p`.

Comentarios

El crecimiento esperado al duplicar la resolucion es cercano a 4x, porque se cuadruplica el numero de pixeles. En path tracing, duplicar N duplica aproximadamente el trabajo por pixel, salvo variaciones por terminacion anticipada y efectos de cache/runtime. La escena con 40 esferas aumenta K y por tanto el costo de cada interseccion, lo que vuelve mas visible el desbalance de carga.

La eficiencia decae al aumentar p por overhead fork-join, barreras implicitas,

planificacion dinamica, contencion de recursos compartidos y saturacion de partes del procesador. En esta tarea no hay reducciones ni escrituras compartidas sobre una misma variable; el principal riesgo de rendimiento es el desbalance y el costo de scheduling con chunks demasiado finos.

Segundo computador

Ejecute el mismo comando completo en otro computador y agregue aqui la tabla y graficos generados. Deben declararse cores fisicos, threads logicos y frecuencia del procesador de ese equipo.
